1 **Title:** The Relationship between Unmet Need for Home and Community-Based Services and  
2 Health and Community Living Outcomes

3  
4 **Abstract:**

5 Background: Few studies have examined user-reported perspectives about the quality and  
6 sufficiency of home and community-based services (HCBS) and their relationship to key health  
7 and community living outcomes.

8  
9 Objective: To examine the association between unmet need for HCBS and health and community  
10 living outcomes in a multi-state, multi-program sample of Medicaid HCBS users.

11  
12 Methods: We used data from the 2017-2018 National Core Indicators-Aging and Disability  
13 (NCI-AD) survey, collected among older adults and adults with physical disabilities who were  
14 receiving Medicaid HCBS across 13 states (N = 10,263). We conducted descriptive analysis on  
15 the demographic, functional, and health characteristics of the sample, and examined the  
16 prevalence of unmet need for HCBS across five domains: 1) assistance with daily activities, 2)  
17 assistive technology, 3) home modifications, 4) transportation, and 5) sufficiency of services for  
18 meeting user needs and goals. We used logistic regressions to estimate adjusted odds ratios for  
19 the association between unmet need for HCBS and health care utilization (ED visits,  
20 hospital/rehab stays, preventative care) and community living outcomes (active in the  
21 community, interacting with family/friends, satisfaction, control).

22  
23 Results: Across the five domains, prevalence of unmet need ranged from 21% (unmet need for  
24 assistance with self-care or other daily activities) to 54% (unmet need for assistive technology).  
25 Individuals who experienced unmet need had consistently worse health and community living  
26 outcomes than those who reported no unmet need, after adjusting for key user demographic,  
27 functional, and social characteristics ( $p < 0.05$ ).

28  
29 Conclusions: Unmet need for HCBS is consistently and significantly associated with poor health  
30 and community living outcomes among Medicaid users.

## 31 Introduction

32 Long-term services and supports (LTSS) refer to a wide range of health and social  
33 services provided to individuals with disabilities and older adults who need assistance with daily  
34 living (i.e. eating, bathing, dressing, medication management, meal preparation, mobility). In the  
35 U.S., LTSS is primarily financed through the Medicaid program, which accounts for over half of  
36 national LTSS spending.<sup>1</sup> An estimated 12 million individuals need LTSS and most prefer to  
37 receive supports at home versus in institutional settings, such as nursing homes.<sup>2,3</sup> Medicaid  
38 Home and Community-Based Services (HCBS) provide an alternative to institutional care,  
39 allowing users to receive LTSS in their own homes and communities.

40 The Americans with Disabilities Act of 1990 (ADA), as reaffirmed by the landmark U.S.  
41 Supreme Court *Olmstead* decision, established that individuals have a right to live in the most  
42 integrated setting appropriate to their needs.<sup>4</sup> Access to HCBS is essential to ensuring this right.  
43 High-quality HCBS provides a tailored set of services to meet users' care and support needs  
44 under their own direction, according to their personal preferences and goals.<sup>5</sup> Services can  
45 include in-home personal care, adult day, employment supports, and assistance with meals,  
46 transportation, assistive devices, and home modifications. While HCBS is not medical care,  
47 services support users' health and well-being by ensuring a safe living environment, assisting  
48 with management of chronic health conditions, and coordinating health care services. HCBS  
49 allow individuals with disabilities to live independently, participate in the community, and age  
50 with dignity and respect. This includes facilitating participation in valued activities and  
51 relationships, as well as employment. Access to HCBS may also reduce unnecessary placements  
52 in more costly nursing homes and other institutional settings.<sup>6-9</sup>

53 Access to Medicaid HCBS is limited. The Medicaid program has a longstanding  
54 institutional bias in which nursing home care is a mandatory benefit, while HCBS are optional  
55 for states to provide.<sup>10-11</sup> Over the past few decades, access to Medicaid HCBS has significantly  
56 expanded. Enforcement of the ADA, coupled with state and federal policies have shifted the  
57 balance of LTSS from institutional to community-based settings.<sup>1, 12-13</sup> Broader access to  
58 Medicaid HCBS is significant because it expands services to individuals who were previously  
59 ineligible for Medicaid LTSS. For example, state Medicaid waivers may extend HCBS services  
60 to certain target populations (e.g., individuals with physical disabilities and older adults) at  
61 higher income thresholds than standard Medicaid rules allow.

62           Nationally, approximately 56% of total Medicaid LTSS spending is now devoted to  
63 HCBS.<sup>12</sup> However, access varies widely between states and across populations that need HCBS.  
64 Moreover, states have significant flexibility in designing their Medicaid HCBS systems, which  
65 contributes to variation in program eligibility and the types and amount of services and supports  
66 provided.<sup>14</sup> Most states cap enrollment in their Medicaid HCBS programs and maintain wait lists.  
67 Nationally, over 820,000 individuals are on wait lists for services covered under 1915 (c) HCBS  
68 waivers (which is the primary Medicaid authority states use to provide HCBS) and 1115 waivers,  
69 and the average wait time exceeds three years.<sup>15-16</sup>

70           Because unmet need for LTSS is not routinely assessed in any national population survey  
71 that includes adults of all ages, unmet need for LTSS is not well understood.<sup>2</sup> In the mid-1990s,  
72 21% of LTSS users in the U.S. were found to have unmet need.<sup>17</sup> Using a broader definition of  
73 LTSS, a 2007 survey among the working-age population in Massachusetts found that unmet need  
74 was as high as 70%.<sup>18</sup> In a 2011 national survey among older adults, 32% of those 65 and older  
75 who had difficulty or received help with self-care or household activities reported experiencing  
76 an adverse consequence related to unmet need.<sup>19</sup> Among participants in Medicaid HCBS  
77 programs, studies across various states have found unmet need ranges from 24% to 58%.<sup>20-22</sup>

78           Previous studies have found that unmet need for HCBS is associated with multiple  
79 adverse outcomes including mortality, hospitalization, and institutionalization.<sup>23-26</sup> Among those  
80 living in community settings, adverse outcomes of unmet LTSS need include the inability to get  
81 out of bed or out into the community, medication mistakes, falls, inadequate nutrition, missed  
82 healthcare appointments, discomfort due to infrequent bathing or changing clothes, and inability  
83 to reach the toilet in time.<sup>17, 27-30</sup>

84           Relatively few studies have examined self-reported perspectives about the quality and  
85 sufficiency of HCBS programs and their relationship to key health outcomes. Moreover, few  
86 studies have examined the impact of unmet needs on community living outcomes, such as the  
87 ability to participate in the community and maintain desired relationships with family and  
88 friends. Prior studies have been limited to data sources focused on older adults receiving  
89 Medicare, but not younger adults with disabilities receiving Medicaid HCBS.<sup>19</sup> Other studies  
90 have been limited to data from single states and/or individuals with disabilities but who are not  
91 necessarily Medicaid HCBS users. Our study builds on previous research by 1) assessing the  
92 prevalence of unmet need for HCBS in a multi-state sample of Medicaid HCBS users and 2)

93 examining the association between unmet need for HCBS and key health and community living  
94 outcomes.

## 96 **Methods**

### 97 *Conceptual Framework*

98 **Figure 1** presents the conceptual framework for the relationship between unmet need for  
99 HCBS and health and community living outcomes. In this model, individual characteristics and  
100 HCBS system-level factors determine the scope and level of services accessed by users.  
101 Individual characteristics include demographics, health characteristics, level of assistance needed  
102 for daily activities, type of residence, and personal preferences and goals. System-level factors  
103 include the design, administration, and quality of Medicaid HCBS program(s) and infrastructure  
104 (note: these characteristics are not directly measured in our study). Across a range of service  
105 domains, users may experience unmet need for HCBS when the level, quality, and/or scope of  
106 services they receive are insufficient for meeting their needs. Users may receive some but not  
107 enough of the supports and services they need in each HCBS domain or report receiving no  
108 services at all. Unmet need for HCBS may put individuals who rely on these services to support  
109 their health, well-being, and community integration at greater risk for poor health and  
110 community outcomes.

111

### 112 *Data*

113 We used secondary data from the 2017-2018 wave of the National Core Indicators Aging  
114 and Disability (NCI-AD) survey. NCI-AD is coordinated by participating states, ADvancing  
115 States (formerly the National Association of States United for Aging and Disabilities  
116 [NASUAD]), and Human Services Research Institute (HSRI). States volunteer to participate in  
117 NCI-AD and choose the publicly funded program(s) to include in their survey sample. Each state  
118 must have at least 400 total respondents to participate. State health agencies conduct the survey  
119 among a sample of older adults and individuals with physical disabilities who access LTSS  
120 through the selected programs in their state.<sup>31</sup> The survey collects a wide range of respondent-  
121 reported information on quality of services and outcomes. Data is collected through in-person  
122 interviews and a subset of questions allow for proxy responses from family, friends, or hired  
123 caregivers (e.g. questions on health care events). Several items are derived from state  
124 administrative records and linked to the survey data, including the primary source of funding for  
125 services.

126           Although the target populations for NCI-AD are older adults and adults with physical  
127 disabilities who use publicly funded LTSS, it is important to note that the individuals sampled  
128 differ across states. While NCI-AD sets general parameters for sampling, individual state  
129 agencies are responsible for administering the NCI-AD. Therefore, sampling and recruitment  
130 procedures may vary by state. States sample respondents from their own set of LTSS programs,  
131 each with varying eligibility criteria. For example, states can choose to draw their samples from  
132 among Medicaid HCBS recipients, Older Americans Act program participants, nursing home  
133 residents, and/or state-funded HCBS program participants.

134           The 2017-2018 NCI-AD represents data collected in one survey cycle (June 1, 2017 –  
135 May 31, 2018) and the data in this study includes responses from 13 states (CO, IN, KS, MN,  
136 MS, NE, NJ, NV, OR, TN, TX, VT and WI). The data was de-identified at the state level to  
137 protect state and respondent identities. See *Table 1* in the supplemental materials for further  
138 details on the Medicaid HCBS program sampled in each state and corresponding sample sizes.

#### 140 *Study sample*

141           Of the 15,789 respondents to the NCI-AD, we limited our sample to the 10,284 identified  
142 as participating in Medicaid HCBS programs. Of those, 21 were removed because of missing  
143 data on all of the outcomes of interest, leaving a final sample size of 10,263 community-dwelling  
144 Medicaid HCBS recipients.

#### 146 *Measures*

147           Outcome Variables – Health Care Utilization & Community Living Outcomes. Health  
148 care utilization and community living outcomes were measured as binary variables (yes/no). The  
149 health care utilization outcomes included measures of whether respondents reported 1) one or  
150 more emergency room visit(s), 2) one or more overnight stay(s) in a hospital or rehabilitation  
151 facility, 3) at least one physical exam or wellness visit, and 4) at least one dental visit over the  
152 prior year. Community living outcomes included measures of whether respondents reported  
153 being 1) as active in the community as they would like to be, 2) able to see or talk to friends and  
154 family when they wanted to, 3) satisfied with how they spend their time during the day, and if  
155 they 4) felt in control of their life. Of note, NCI-AD allows proxy responses for survey items  
156 used to construct the health care utilization outcomes but not the community living outcomes.

157            Independent Variables – Unmet Need. The key independent variables were binary  
158 (yes/no) indicators of unmet need for HCBS. Unmet need was assessed across five domains: 1)  
159 assistance with self-care or other daily activities, 2) assistive technology, 3) home modifications,  
160 4) transportation, and 5) services that fully meet user needs and goals. Respondents had 1) unmet  
161 need for assistance with self-care or other daily activities if they did not always receive enough  
162 help with self-care activities (e.g., bathing, dressing, eating) or other daily activities (e.g.,  
163 preparing meals, shopping, taking medications) when needed. Respondents had 2) unmet need  
164 for assistive technology if they needed but did not have any of the following items: walker,  
165 scooter, wheelchair, hearing aids, glasses, or CPAP machine. Similarly, respondents had 3)  
166 unmet need for home modifications if they needed but did not have any of the following items:  
167 bathroom grab bars, other bathroom modifications, specialized bed, ramp or chairlift, remote  
168 monitoring system, or emergency response system. For transportation, respondents had 4) unmet  
169 need if they reported not always having transportation to medical appointments or activities  
170 outside of the home. Finally, respondents had 5) unmet need for services that met their needs and  
171 goals if they reported that their long-term care services did not fully meet all of their needs and  
172 goals.

173            Covariates. We examined several demographic and health characteristics of the sample  
174 and included these as covariates in our multivariate analyses. Demographic characteristics  
175 included age, gender, race/ethnicity (white, Black, and other non-Hispanic, Hispanic, unknown),  
176 and location (rural or urban area based on respondent zip codes). This information was derived  
177 from state administrative records, and where missing, was asked during the interview. We also  
178 included two variables on living arrangements: whether the respondent lived alone and residence  
179 type (home or senior living, congregate setting [e.g., group home or assisted living], other).  
180 Health characteristics included self-reported health status (excellent, very good, or good; fair;  
181 poor; only included as a covariate in models for community living outcomes) and functional  
182 status based on reported level of need (none, some, a lot) for assistance with self-care and other  
183 daily activities.

184

185 *Analysis*

186            We conducted descriptive analysis to describe the demographic, functional, and health  
187 characteristics of the sample overall and by unmet need status (i.e., any unmet need vs. no unmet

188 need) to examine how individual characteristics might be associated with unmet need. We also  
189 performed bivariate analyses to determine the observed prevalence of each outcome by unmet  
190 need status. We used logistic regressions to estimate the adjusted odds ratios (with 95%  
191 confidence intervals) for the association between unmet need indicators and the health care  
192 utilization and community living outcomes, as hypothesized in our conceptual framework.  
193 Multivariable models adjusted for the person-level characteristics described above, as these  
194 factors may also influence health and community living outcomes. We performed all analyses in  
195 Stata version 16 MP and a p-value of  $<0.05$  was the accepted level of significance. This study  
196 was reviewed and approved by the authors' Institutional Review Board.

## 197 Results

198 *Table 1* presents descriptive statistics on the community-dwelling Medicaid HCBS users  
199 in the study sample, overall and by unmet need status. About 80% of users reported unmet need  
200 in at least one domain, and unmet need for assistive technology and home modifications were  
201 most common. In general, those with any unmet need were younger than those without unmet  
202 need. HCBS users who were non-Hispanic white represented a greater proportion of those with  
203 no unmet need compared to those with any unmet need, and the inverse relationship was true for  
204 all other racial/ethnic groups. Living at home/senior living and living alone was more common  
205 among individuals reporting unmet need. Individuals with any unmet need were more likely to  
206 report their health status as poor.

207 *Figure 2* compares the observed prevalence of each health and community living  
208 outcome among HCBS users with any unmet need to those with no unmet need in any of the five  
209 domains. Individuals with at least one type of unmet need had greater prevalence of ER use and  
210 overnight hospital or rehab stays (52% vs. 34% and 36% vs. 24%, respectively). Individuals with  
211 no unmet need were more likely to receive preventative care services (i.e., a physical or dental  
212 exam). With respect to community living, users with no unmet need were consistently more  
213 likely to experience each positive outcome than those with any unmet need.

214 *Table 2* presents results from multivariate analysis that examines the association between  
215 unmet need and health care utilization outcomes, adjusted for respondent characteristics. In  
216 general, unmet need was associated with greater likelihood of an ER visit and a hospital/rehab  
217 stay in the past year and reduced likelihood of both types of preventative care in the past year.  
218 Among the various types of unmet need, lack of adequate assistive technology was associated  
219 with the greatest likelihood of having an ER visit and a hospital/rehab stay, and lowest likelihood  
220 of receiving a physical exam in the last year. Unmet need for transportation was associated with  
221 the lowest likelihood of receiving a dental exam in the last year.

222 *Table 3* presents the adjusted association between the various types of unmet need and  
223 community living outcomes. Unmet need was consistently associated with lower likelihood of  
224 experiencing each community living outcome. Comparing across types of unmet need, unmet  
225 need for transportation was related to the lowest likelihood of being active in the community and  
226 interacting with friends and family. Services that did not fully meet recipient needs and goals

227 was associated with the lowest likelihood of user satisfaction with how time is spent and feeling  
228 in control of life.

Journal Pre-proof

## 229 Discussion

230 This study examines the prevalence of unmet needs and associated health and community  
231 living outcomes in a multi-state, multi-program sample of older adults and individuals with  
232 physical disabilities receiving Medicaid HCBS. Using a novel dataset that assesses LTSS  
233 outcomes across a standard set of user-reported measures, we found that unmet need for HCBS is  
234 common among older adults and adults with physical disabilities who receive Medicaid HCBS.  
235 While our study does not focus on the causes for unmet need, our conceptual framework presents  
236 HCBS system-level characteristics as a factor in the ability of HCBS programs to meet users'  
237 service and support needs. The prevalence of unmet needs for HCBS is unsurprising given the  
238 optional nature of most services under state Medicaid programs, enrollment caps, and limits on  
239 service allocations. Access to HCBS may also be linked to systemic racial and ethnic barriers,  
240 and barriers by geographic location.<sup>32-33</sup> Furthermore, challenges with provider networks and the  
241 availability of qualified direct care workers may also impact access to high-quality HCBS.  
242 Demographic shifts have increased reliance on direct care workers as the need for LTSS grows  
243 and the supply of potential family caregivers falls.<sup>34</sup> At the same time, many direct care workers  
244 experience poor job quality, including low wages, limited benefits, and insufficient training,  
245 leading to high employee turnover and job vacancies.<sup>35-38</sup> These workforce issues may impact the  
246 quality of HCBS and lead to unmet need and other adverse outcomes.<sup>38-39</sup>

247 Our finding that nearly a third of HCBS users reported that their services did not fully  
248 meet their service needs and goals is particularly concerning given that the Centers for Medicaid  
249 and Medicare Services requires person-centered planning for all individuals receiving Medicaid  
250 HCBS. Person-centered planning is a facilitated, individual-directed, positive approach to  
251 planning and coordinating a person's services and supports based on their individual aspirations,  
252 needs, preferences, and values.<sup>5, 40</sup> The extent to which person-centered thinking, planning, and  
253 practice is implemented effectively varies considerably across HCBS programs and states. Lack  
254 of high-quality person-centered planning may impact the degree to which services and supports  
255 can be customized to fully meet individual needs. To address this variation, policy makers should  
256 adopt and enforce a set of standardized person-centered planning practices and measures to  
257 improve the quality of service planning among HCBS users.<sup>5</sup> Future studies should examine the  
258 barriers and facilitators of person-centered planning among Medicaid HCBS recipients and

259 assess the extent to which service plans are implemented and reflected in the supports that users  
260 receive.

261 Our study found that unmet need for HCBS was consistently associated with adverse  
262 health and community living outcomes, supporting the relationships hypothesized in our  
263 conceptual framework. The link between unmet need and user outcomes provides actionable  
264 evidence for policy makers to systematically assess and address individual users' specific need  
265 for HCBS. A crucial concern in the growth of HCBS is whether community-based supports  
266 result in improved outcomes for users over institutional care. Among individuals dually eligible  
267 for Medicaid and Medicare, both all-cause hospitalizations and potentially avoidable  
268 hospitalizations are more common among HCBS users than nursing home residents.<sup>41</sup> Results  
269 from our study suggest that addressing unmet needs among HCBS users could be one pathway  
270 for reducing avoidable hospitalizations and improving health and well-being, which could reduce  
271 overall health care costs for this population. This finding is particularly relevant for state and  
272 federal initiatives seeking to better integrate and coordinate LTSS and acute care for individuals  
273 receiving Medicaid LTSS. There has been significant growth in Managed Long-Term Services  
274 and Supports (MLTSS), which is the delivery of LTSS through capitated managed care  
275 organizations that are also typically responsible for acute care and other services such as  
276 behavioral health.<sup>42-43</sup> With meaningful stakeholder engagement, oversight, and quality metrics,  
277 these payment and delivery models could offer health plans better incentive to reduce unmet  
278 HCBS needs and potentially improve related health outcomes among their beneficiaries.<sup>44</sup>

279 This study has several limitations. The cross-sectional design limits our ability to make  
280 causal inferences about the relationship between unmet need and outcomes for HCBS users.  
281 For example, because the cross-sectional data does not ensure the temporal precedence of unmet  
282 need, there is possibility for reverse causality. Although the multivariate analysis controlled for  
283 certain respondent health and functional characteristics, it is possible that health and community  
284 living outcomes may contribute to a user's unmet need for HCBS. State-level administration of  
285 the NCI-AD survey presents another limitation for generalizability of the study findings.  
286 Participating states did not have identical sampling strategies and selected respondents from their  
287 own set of unique Medicaid HCBS programs, each with their own user eligibility requirements.<sup>33</sup>  
288 The study sample may not be representative of the Medicaid HCBS user population in each state  
289 or across states.

290           Because the data was aggregated across states (without the presence of a state identifier),  
291 the extent to which various state Medicaid program characteristics might differentially impact  
292 unmet need among HCBS users, user outcomes, or the relationship between the two is unknown.  
293 Prior research involving the Medicaid population has found wide variation between states in  
294 terms of program sufficiency and quality. Finally, because some survey items allowed for proxy  
295 responses, not all data collected by NCI-AD was user-reported. There may be cases where proxy  
296 responses do not accurately or fully capture user experiences.

297           Despite these limitations, the findings from this study emphasize the heightened risk of  
298 adverse health and community living outcomes related to unmet needs for HCBS among  
299 Medicaid beneficiaries. This study calls attention to the importance of user perspectives and  
300 community engagement as important measures for assessing the sufficiency, quality, and  
301 outcomes of HCBS programs. It also underscores the importance of person-centered approaches  
302 that incorporate the perspectives, needs, and desires of individuals receiving HCBS and the  
303 potential impact on health and community living outcomes. As states are working to shift LTSS  
304 programs away from institutional services and toward HCBS, additional efforts are needed to  
305 ensure that Medicaid HCBS programs are addressing the service needs of their beneficiaries.  
306 Programs should implement quality measures that track the extent to which recipients' needs are  
307 being met, in addition to whether the services they receive have been designed to further their  
308 individual life goals.
